

Field Theory

Coulomb's and Ampere's Laws of Force describe an "action at a distance" approach to describing the basic electromagnetic forces. In this approach, we can state:

1. A **charge** at one location in space will exert a force on a **charge** at another location in space.
2. **Current** flowing at one location in space will exert a force on **current** flowing at another location in space.

Alternatively, we can use a "field theory" of electromagnetics. In this field theory, we describe the forces in this manner:

1. A **charge** at one location in space will create an **electric (vector) field** at any and all other locations in space.

This **field** will then exert a force on any other **charges** that exist in space.

2. **Current** flowing at one location in space will create a **magnetic flux density (vector) field** at any and all other locations in space.

This **field** will then exert a force on any other **current** that exist in space.

In other words, in **field theory**, we state that **sources create fields** (everywhere)—and then the **fields apply the force** to other charges or currents!

Q: *Good Heavens! This seems to make electromagnetics even more difficult! Why do we use the concept of electric and magnetic fields??*

A: Field theory is helpful because it allows us to **divide** the electromagnetic force problem into **two** more manageable pieces. Specifically:

We can determine the **fields** generated by **source** charges or currents, **without** every having to consider the other charges or currents that they affect!

We can determine the effect (i.e., **forces**) of fields on charges or currents, **without** every having to consider the sources that created those fields!
