$v_i(t)$ 

 $4.0 V^{-}$ 

# Example: A Small-Signal Analysis of a MOSFET Amplifier

Let's again consider this simple NMOS Amplifier:

We can perform a small-signal analysis to determine the small-signal open-circuit voltage gain  $A_o$ :

$$A_o = \frac{V_o(t)}{V_i(t)}$$

Jim Stiles The Univ. of Kansas Dept. of EECS

## Step 1: DC Analysis

Turning off the small signal source leaves a DC circuit of:

We ASSUME saturation, so that we ENFORCE:

$$I_D = K (V_{GS} - V_t)^2$$

 $R_D = 5K$ 

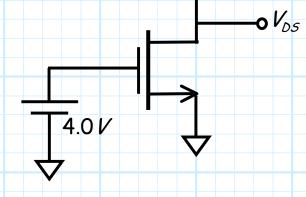

15.0 V

It is evident that:

$$V_{GS} = 4.0 \text{ V}$$

Therefore the DC drain current is:

$$I_D = K (V_{GS} - V_{t})^2$$
  
= 0.25(4-2)<sup>2</sup>  
= 1.0 mA

Thus, the DC voltage  $V_{DS}$  can be determined from KVL as:

$$V_{DS} = 15.0 - I_{D}R_{D}$$
  
= 15.0 - 1(5)  
= 10.0 V

We CHECK our results and find:

$$V_{GS} = 4.0 > V_{t} = 2.0$$

and:

$$V_{DS} = 10.0 > V_{GS} - V_{t} = 2.0$$

# Step 2: Determine the small-signal parameters

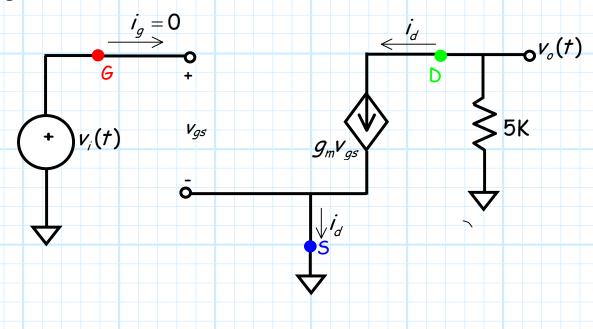

We find that the transconductance is:

$$g_m = 2K(V_{GS} - V_f)$$
  
= 2(0.25)(4.0 - 2.0)  
= 1 mA/V

Note that **no** value of  $\lambda$  was given, so we will assume  $\lambda=0$ , and thus **output resistance**  $r_o=\infty$ .

# Steps 3 and 4: Determine the small-signal circuit

We now turn off the **two** DC voltage source, and replace the MOSFET with its **small signal model**. The result is our **small-signal circuit**:

## Step 5: Analyze the small-signal circuit

The analysis of this small-signal circuit is fairly straightforward. First, we note that:

$$V_{qs} = V_i$$

and that:

$$i_d = g_m v_{gs}$$

$$= 1.0 v_{gs}$$

$$= v_{gs}$$

and that:

$$v_o = -5i_d$$

Combing these equations, we find that:

$$v_o = -5 v_i$$

And thus the small-signal open-circuit voltage gain of this amplifier is:

$$A_o = \frac{v_o(t)}{v_i(t)} = -5.0$$
