# Improved Semi-Online Makespan Scheduling with a Reordering Buffer 

Hongyang Sun (Speaker)

Joint work with Rui Fan
Nanyang Technological University, Singapore

## Background

- Classical online scheduling
- Schedule a sequence of jobs arriving one by one on $m$ identical machines to minimize makespan
- List scheduling algorithm (Graham 1966)
- Assign arriving job on a machine with least load
- (2-1/m)-competitive
- Best known competitive ratio of deterministic algorithm [1.88, 1.9201] for large $m$

## Background

- Semi-online scheduling with reordering buffer
- A buffer of limited size $k$ (independent of input size) can be used to store and reorder jobs
- Store: If buffer is not full, we can admit a new job into the buffer without assigning any job to any machine
- Reorder: If buffer is full, we can select any job from the buffer or the arriving job and assign it to a machine

## Results

- Semi-online scheduling with reordering buffer
- For $m=2$, optimal comp. ratio $=4 / 3$ (Kellerer et al. $1997 \&$ Zhang 1997) using $k=1$, the smallest possible buffer size

## Results

- Semi-online scheduling with reordering buffer
- For $m=2$, optimal comp. ratio $=4 / 3$ (Kellerer et al. 1997 \& Zhang 1997) using $k=1$, the smallest possible buffer size
- For general $m$, optimal comp. ratio (lower bound) $=r_{m}$ (Englert, Ozmen and Westermann 2008)
- $r_{m}$ is the solution to the following equation

$$
\left\lceil\left(r_{m}-1\right) m / r_{m}\right\rceil \cdot r_{m} / m+\left(r_{m}-1\right) \cdot \sum_{i=\left\lceil\left(r_{m}-1\right) m / r_{m}\right\rceil}^{m-1} 1 / i=1
$$

## Results

- Semi-online scheduling with reordering buffer
- For $m=2$, optimal comp. ratio $=4 / 3$ (Kellerer et al. 1997 \& Zhang 1997) using $k=1$, the smallest possible buffer size
- For general $m$, optimal comp. ratio (lower bound) $=r_{m}$ (Englert, Ozmen and Westermann 2008)
- $r_{m}$ is the solution to the following equation

$$
\left\lceil\left(r_{m}-1\right) m / r_{m}\right\rceil \cdot r_{m} / m+\left(r_{m}-1\right) \cdot \sum_{i=\left\lceil\left(r_{m}-1\right) m / r_{m}\right\rceil}^{m-1} 1 / i=1
$$

- $r_{m}$ is a monotonically increasing function of $m$
- $r_{2}=4 / 3$, and
$\lim _{m \rightarrow \infty} r_{m} \approx 1.4659$

## Results

- Semi-online scheduling with reordering buffer
- For general $m$, optimal comp. ratio (lower bound) $=r_{m}$ (Englert, Ozmen and Westermann 2008)
- $\boldsymbol{k}=\boldsymbol{O}(\boldsymbol{m})$ is necessary and sufficient to achieve $r_{m}$
- A $r_{m}$-comp. algorithm was proposed with a reordering buffer of size $\boldsymbol{k}=\left(\mathbf{1 + 2} / r_{m}\right) \boldsymbol{m} \approx \mathbf{2 . 3 6 4 m}$ for large $m$
- A lower bound of $\boldsymbol{k}=\boldsymbol{m} / \mathbf{2}$ on the buffer size

## Results

- Semi-online scheduling with reordering buffer
- For general $m$, optimal comp. ratio (lower bound) $=r_{m}$ (Englert, Ozmen and Westermann 2008)
- $\boldsymbol{k}=\boldsymbol{\Theta}(\boldsymbol{m})$ is necessary and sufficient to achieve $r_{m}$
- A $r_{m}$-comp. algorithm was proposed with a reordering buffer of size $\boldsymbol{k}=\left(\mathbf{1 + 2} / r_{m}\right) \boldsymbol{m} \approx \mathbf{2 . 3 6 4 m}$ for large $m$
- A lower bound of $\boldsymbol{k}=\boldsymbol{m} / \mathbf{2}$ on the buffer size
- What is the exact buffer size required to achieve $r_{m}$ ?

## Results

- Semi-online scheduling with reordering buffer
- For general $m$, optimal comp. ratio (lower bound) $=r_{m}$ (Englert, Ozmen and Westermann 2008)
- $\boldsymbol{k}=\boldsymbol{\Theta}(\boldsymbol{m})$ is necessary and sufficient to achieve $r_{m}$
- A $r_{m}$-comp. algorithm was proposed with a reordering buffer of size $\boldsymbol{k}=\left(\mathbf{1 + 2} / r_{m}\right) \boldsymbol{m} \approx \mathbf{2 . 3 6 4 m}$ for large $m$
- A lower bound of $\boldsymbol{k}=\boldsymbol{m} / \mathbf{2}$ on the buffer size
- What is the exact buffer size required to achieve $r_{m}$ ?

Our result improves the required buffer size

- A $r_{m}$-comp. algo. with a buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m} \approx 2.068 m$ for large $m$, improving the previous result by $\approx 0.296 m$

## Outline

- Lower bound $r_{m}$
- A scheduling framework to get optimal comp. ratio
- Buffer size $\boldsymbol{k}=\left(\mathbf{1 + 2} / r_{m}\right) \boldsymbol{m} \approx \mathbf{2 . 3 6 4 m}$ (Englert et al.)
- Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m} \approx \mathbf{2 . 0 6 8 m}$ (Our result)
- Tradeoff between comp. ratio and buffer size
- Remarks

## Lower bound $r_{m}$

- Consider the following load profile (weight $w_{i}$ )
- $w_{i}=\min \left\{r_{m} / m,\left(r_{m}-1\right) / i\right\}$, where $\sum w_{i}=1$

## Lower bound $r_{m}$

- Consider the following load profile (weight $w_{i}$ )
- $w_{i}=\min \left\{r_{m} / m,\left(r_{m}-1\right) / i\right\}$, where $\sum w_{i}=1$
- Arbitrarily small jobs of total size $1+\varepsilon$ arrive
- Buffer contains size $=\varepsilon$, and total assigned job size $=1$

## Lower bound $\boldsymbol{r}_{\boldsymbol{m}}$

- Consider the following load profile (weight $w_{i}$ )
- $w_{i}=\min \left\{r_{m} / m,\left(r_{m}-1\right) / i\right\}$, where $\sum w_{i}=1$
- Arbitrarily small jobs of total size $1+\varepsilon$ arrive
- Buffer contains size $=\varepsilon$, and total assigned job size $=1$
- There must be a machine $j$ with load $\geq w_{j}$, otherwise $\sum w_{i}<1$

## Lower bound $\boldsymbol{r}_{\boldsymbol{m}}$

- Consider the following load profile (weight $w_{i}$ )
- $w_{i}=\min \left\{r_{m} / m,\left(r_{m}-1\right) / i\right\}$, where $\sum w_{i}=1$
- Arbitrarily small jobs of total size $1+\varepsilon$ arrive
- Buffer contains size $=\varepsilon$, and total assigned job size $=1$
- There must be a machine $j$ with load $\geq w_{j}$, otherwise $\sum w_{i}<1$
- If $w_{j}=r_{m} / m$, no more job arrives
$\rightarrow$ OPT $=1 / m, \mathrm{ALG} \geq r_{m} / m$

## Lower bound $\boldsymbol{r}_{\boldsymbol{m}}$

- Consider the following load profile (weight $w_{i}$ )
- $w_{i}=\min \left\{r_{m} / m,\left(r_{m}-1\right) / i\right\}$, where $\sum w_{i}=1$
- Arbitrarily small jobs of total size $1+\varepsilon$ arrive
- Buffer contains size $=\varepsilon$, and total assigned job size $=1$
- There must be a machine $j$ with load $\geq w_{j}$, otherwise $\sum w_{i}<1$
- If $w_{j}=r_{m} / m$, no more job arrives
$\rightarrow$ OPT $=1 / m, \mathrm{ALG} \geq r_{m} / m$
- If $w_{j}=\left(r_{m}-1\right) / j, m-j$ large jobs of size $1 / j$ arrive
$\rightarrow \mathrm{OPT}=1 / j, \mathrm{ALG} \geq\left(r_{m}-1\right) / j+1 / j=r_{m} / j$

## Lower bound $\boldsymbol{r}_{\boldsymbol{m}}$

- Consider the following load profile (weight $w_{i}$ )
- $w_{i}=\min \left\{r_{m} / m,\left(r_{m}-1\right) / i\right\}$, where $\sum w_{i}=1$
- Arbitrarily small jobs of total size $1+\varepsilon$ arrive
- Buffer contains size $=\varepsilon$, and total assigned job size $=1$
- There must be a machine $j$ with load $\geq w_{j}$, otherwise $\sum w_{i}<1$
- If $w_{j}=r_{m} / m$, no more job arrives $\rightarrow$ OPT $=1 / m, \mathrm{ALG} \geq r_{m} / m$
- If $w_{j}=\left(r_{m}-1\right) / j, m-j$ large jobs of size $1 / \mathrm{j}$ arrive
$\rightarrow$ OPT $=1 / j$, ALG $\geq\left(r_{m}-1\right) / j+1 / j=r_{m} / j$

- In both cases, competitive ratio $\geq r_{m}$

## A scheduling framework to get optimal

 comp. ratio- Three phases:
- (1) Initial phase: Admit $k$ jobs into buffer w/o assignment

## A scheduling framework to get optimal

 comp. ratio- Three phases:
- (1) Initial phase: Admit $k$ jobs into buffer w/o assignment
- (2) Iterative phase: Admit a new job, and pick a smallest job and assign it to some machine $j$

## A scheduling framework to get optimal comp. ratio

- Three phases:
- (1) Initial phase: Admit $k$ jobs into buffer w/o assignment
- (2) Iterative phase: Admit a new job, and pick a smallest job and assign it to some machine $j$
- Choice of the machine depends on the algorithm
- Maintain a profile of machine loads related to $\boldsymbol{w}_{i}=\min \left\{r_{m} / m,\left(r_{m}-1\right) / i\right\}$, where normalized total area $=1$, i.e., $\sum w_{i}=1$

## A scheduling framework to get optimal

 comp. ratio(3) Final phase

## A scheduling framework to get optimal comp. ratio

(3) Final phase

- $1^{\text {st }}$ Step: Large jobs (size > 1/3.OPT)
- Make an optimal schedule (LPT)
- Sort in ascending order of size
- Place them on current schedule

## A scheduling framework to get optimal comp. ratio

- (3) Final phase
- $1^{\text {st }}$ Step: Large jobs (size > 1/3.OPT)
- Make an optimal schedule (LPT)
- Sort in ascending order of size
- Place them on current schedule
$\rightarrow$ Mathematics can ensure the
 optimal comp. ratio $r_{m}$

## A scheduling framework to get optimal comp. ratio

- (3) Final phase
- $1^{\text {st }}$ Step: Large jobs (size $>1 / 3.0 \mathrm{PT}$ )
- Make an optimal schedule (LPT)
- Sort in ascending order of size
- Place them on current schedule
$\rightarrow$ Mathematics can ensure the optimal comp. ratio $r_{m}$
- $\mathbf{2}^{\text {nd }}$ Step: Small jobs (size $\leq 1 / 3.0 P T$ )
- Place one by one greedily
- $\leq$ OPT $+1 / 3 \cdot$ OPT $\leq r_{m} \cdot$ OPT
$\rightarrow$ Still optimal comp. ratio

## Buffer size $\boldsymbol{k}=\mathbf{3 m}$ (Englert et al.)

Iterative phase: Assign smallest job of size $p$ to a machine $\boldsymbol{j}$ with load $L_{j} \leq \boldsymbol{w}_{j} \cdot(T+m \cdot p)-\boldsymbol{p}$

## Buffer size $\boldsymbol{k}=\mathbf{3 m}$ (Englert et al.)

Iterative phase: Assign smallest job of size $p$ to a machine $\boldsymbol{j}$ with load $L_{j} \leq \boldsymbol{w}_{j} \cdot(T+m \cdot p)-p$

- This is feasible with at least $m$ buffer space (proof by contradiction)
- After Iterative phase: no machine exceeds the profile defined on $T_{\text {final }}+m \cdot p$

## Buffer size $\boldsymbol{k}=3 \boldsymbol{m}$ (Englert et al.)

Iterative phase: Assign smallest job of size $p$ to a machine $\boldsymbol{j}$ with load $L_{j} \leq \boldsymbol{w}_{j} \cdot(T+m \cdot p)-\boldsymbol{p}$

- This is feasible with at least $m$ buffer space (proof by contradiction)
- After Iterative phase: no machine exceeds the profile defined on $T_{\text {final }}+m \cdot p$
- Final phase: at most $2 m$ large job form an optimal schedule $L^{\prime}{ }_{1} \leq L^{\prime}{ }_{2} \leq \ldots \leq L_{m}^{\prime}$

## Buffer size $\boldsymbol{k}=3 \boldsymbol{m}$ (Englert et al.)

Iterative phase: Assign smallest job of size $p$ to a machine $\boldsymbol{j}$ with load $L_{j} \leq \boldsymbol{w}_{j} \cdot(T+m \cdot p)-\boldsymbol{p}$

- This is feasible with at least $m$ buffer space (proof by contradiction)
- After Iterative phase: no machine exceeds the profile defined on $T_{\text {final }}+m \cdot p$
- Final phase: at most $2 m$ large job form an optimal schedule $L^{\prime}{ }_{1} \leq L^{\prime}{ }_{2} \leq \ldots \leq L^{\prime}{ }_{m}$

$$
\text { For all } 0 \leq j \leq m-1
$$

$$
\left.\begin{array}{rl}
O P T & \geq\left(T_{\text {final }}+m \cdot p+\sum L^{\prime}\right) / m \\
L_{j} & \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime}
\end{array}\right\} \longmapsto L_{j} \leq r_{m} \cdot O P T
$$

## Buffer size $\boldsymbol{k}=3 \boldsymbol{m}$ (Englert et al.)

## Mathematics to prove the $1^{\text {st }}$ step of the final phase:

For all $0 \leq j \leq m-1$

$$
\left.\begin{array}{rl}
O P T & \geq\left(T_{\text {final }}+m \cdot p+\sum L_{i}^{\prime}\right) / m \\
L_{j} & \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime}
\end{array}\right\} \Longrightarrow L_{j} \leq r_{m} \cdot O P T
$$

For $\left(r_{m}-1\right) m / r_{m} \leq j \leq m-1, w_{j}=\left(r_{m}-1\right) / j$. For $0 \leq j \leq\left(r_{m}-1\right) m / r_{m}, w_{j}=r_{m} / m$

$$
\begin{aligned}
L_{j} & \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-\sum L_{i}^{\prime}\right)+L_{j}^{\prime} \\
& \leq\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-(m-j) L_{j}^{\prime}\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-m L_{j}^{\prime}+j L_{j}^{\prime}\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-m L_{j}^{\prime}\right)+r_{m} L_{j}^{\prime}
\end{aligned}
$$

$$
L_{j} \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime}
$$

$$
\leq r_{m} / m \cdot\left(m O P T-\Sigma L_{i}^{\prime}\right)+L_{j}^{\prime}
$$

$$
\leq r_{m} / m \cdot\left(m \text { OPT }-(m-j) L_{j}^{\prime}\right)+L_{j}^{\prime}
$$

$$
=r_{m} / m \cdot\left(m \text { OPT }-m / r_{m} L_{j}^{\prime}\right)+L_{j}^{\prime}
$$

$$
=r_{m} \cdot O P T
$$

## Buffer size $\boldsymbol{k}=3 \boldsymbol{m}$ (Englert et al.)

## Mathematics to prove the $1^{\text {st }}$ step of the final phase:

For all $0 \leq j \leq m-1$

$$
\left.\begin{array}{rl}
O P T & \geq\left(T_{\text {final }}+m \cdot p+\sum L_{i}^{\prime}\right) / m \\
L_{j} & \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime}
\end{array}\right\} \Longrightarrow L_{j} \leq r_{m} \cdot O P T
$$

- For $\left(r_{m}-1\right) m / r_{m} \leq j \leq m-1, w_{j}=\left(r_{m}-1\right) / j$ For $0 \leq j \leq\left(r_{m}-1\right) m / r_{m}, w_{j}=r_{m} / m$

$$
\begin{aligned}
L_{j} & \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-\Sigma L_{i}^{\prime}\right)+L_{j}^{\prime} \\
& \leq\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-(m-j) L_{j}^{\prime}\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-m L_{j}^{\prime}+j L_{j}^{\prime}\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-m L_{j}^{\prime}\right)+r_{m} L_{j}^{\prime} \\
& \leq r_{m} / m \cdot\left(m \text { OPT }-m L_{j}^{\prime}\right)+r_{m} L_{j}^{\prime} \\
& =r_{m} \cdot O P T
\end{aligned}
$$

Similar derivations carry over to the other algorithms

## Buffer size $\boldsymbol{k}=\left(\mathbf{1}+\mathbf{2} / r_{m}\right) \boldsymbol{m}$ (Englert et al.)

- Same algorithm: Requires a buffer size $\approx 2.364 m$ for large $m$

## Buffer size $\boldsymbol{k}=\left(\mathbf{1 + 2} / r_{m}\right) \boldsymbol{m}$ (Englert et al.)

- Same algorithm: Requires a buffer size $\approx 2.364 \mathrm{~m}$ for large $m$
- Observation: The following needs only hold for the $m / r_{m}$ processors on the right, since the profile on the left is flat

$$
\left.\begin{array}{|l|l}
\text { For }\left(r_{m}-1\right) m / r_{m} \leq j \leq m-1 & O P T \\
\geq\left(T_{\text {final }}+m \cdot p+\sum L_{i}^{\prime}\right) / m \\
L_{j} \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime}
\end{array}\right\} \quad \Rightarrow \quad L_{j} \leq r_{m} \cdot O P T
$$

## Buffer size $\boldsymbol{k}=\left(\mathbf{1 + 2} / r_{m}\right) \boldsymbol{m}$ (Englert et al.)

Same algorithm: Requires a buffer size $\approx 2.364 \mathrm{~m}$ for large m

- Observation: The following needs only hold for the $m / r_{m}$ processors on the right, since the profile on the left is flat

$$
\begin{array}{|l|l}
\text { For }\left(r_{m}-1\right) m / r_{m} \leq j \leq m-1 & \left.\begin{array}{rl}
O P T & \geq\left(T_{\text {final }}+m \cdot p+\sum L^{\prime}\right) / m \\
L_{j} & \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime}
\end{array}\right\}
\end{array} \Rightarrow L_{j} \leq r_{m} \cdot O P T
$$

These processors get at most 2 jobs each according to the optimal LPT rule, so total extra buffer space required is $2 \mathrm{~m} / r_{m}$

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

- Observation: In the iterative phase, it is not necessary to maintain a uniform load profile for all processors, or more precisely for the $\mathrm{m} / r_{m}$ processors on the right, in order to satisfy the following in the final phase

$$
\left.\left.\left.\begin{array}{|cc}
\text { For }\left(r_{m}-1\right) m / r_{m} \leq j \leq m-1 & \left.\begin{array}{c}
\text { OPT } \geq \\
\\
L_{j} \leq T_{\text {final }}+m \cdot p+\sum L_{j} \cdot
\end{array}\right) / m \\
\text { final }
\end{array}\right)+m \cdot p\right)+L_{j}^{\prime}\right\} ~ \Longrightarrow L_{j} \leq r_{m} \cdot \text { OPT }
$$

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

- Observation: In the iterative phase, it is not necessary to maintain a uniform load profile for all processors, or more precisely for the $\mathrm{m} / r_{m}$ processors on the right, in order to satisfy the following in the final phase

$$
\text { For } \left.\left(r_{m}-1\right) m / r_{m} \leq j \leq m-1 \quad \begin{array}{r}
O P T \geq\left(T_{\text {final }}+m \cdot p+\sum L_{i}^{\prime}\right) / m \\
L_{j} \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime}
\end{array}\right\} \Longrightarrow L_{j} \leq r_{m} \cdot O P T
$$

- Design a non-uniform profile: Observe from the proof of the final phase For $\left(r_{m}-1\right) m / r_{m} \leq j \leq m-1, w_{j}=\left(r_{m}-1\right) / j$

$$
\begin{aligned}
L_{j} & \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-\sum L_{i}^{\prime}\right)+L_{j}^{\prime} \\
& \leq\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-(m-j) L_{j}^{\prime}\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-m L_{j}^{\prime}+j L_{j}^{\prime}\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-m L_{j}^{\prime}\right)+r_{m} L_{j}^{\prime} \\
& \leq r_{m} / m \cdot\left(m \text { OPT }-m L_{j}^{\prime}\right)+r_{m} L_{j}^{\prime} \\
& =r_{m} \cdot O P T
\end{aligned}
$$

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

- Observation: In the iterative phase, it is not necessary to maintain a uniform load profile for all processors, or more precisely for the $\mathrm{m} / r_{m}$ processors on the right, in order to satisfy the following in the final phase

$$
\begin{array}{lr}
\text { For }\left(r_{m}-1\right) m / r_{m} \leq j \leq m-1 & \left.\begin{array}{rl}
O P T & \left(T_{\text {final }}+m \cdot p+\sum L_{i}^{\prime}\right) / m \\
L_{j} \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime}
\end{array}\right\} \Longrightarrow L_{j} \leq r_{m} \cdot O P T
\end{array}
$$

- Design a non-uniform profile: Observe from the proof of the final phase

$$
\begin{aligned}
& \begin{aligned}
\text { For }\left(r_{m}-1\right) m / r_{m} \leq j \leq m-1, w_{j}=\left(r_{m}-1\right) / j \\
L_{j} \leq w_{j} \cdot\left(T_{\text {final }}+m \cdot p\right)+L_{j}^{\prime}
\end{aligned} \quad \rightarrow \sum L_{i}^{\prime} \geq(m-j) L_{j,}^{\prime} \text {, giving up } L_{1}^{\prime} \text { to } L_{j-1}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT } \Sigma \Sigma L_{i}^{\prime}\right)+L_{j}^{\prime} \\
& \leq\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-(m-j) L_{i}^{\prime}\right)-L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-m L_{j}^{\prime}+j L_{j}^{\prime}\right)+L_{j}^{\prime} \\
& =\left(r_{m}-1\right) / j \cdot\left(m \text { OPT }-m L_{j}^{\prime}\right)+r_{m} L_{j}^{\prime} \\
& \leq r_{m} / m \cdot\left(m \text { OPT }-m L_{j}^{\prime}\right)+r_{m} L_{j}^{\prime} \\
& =r_{m} \text {. OPT }
\end{aligned}
$$

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

Iterative phase: Assign smallest job of size $p$ to a machine $j$ with load $\leq w_{j} \cdot\left(T+k-2\left(m-j^{\prime}\right) p\right)-p$, where $j^{\prime}=\max \left\{j,\left(r_{m}-1\right) m / r_{m}\right\}$

## Buffer size $\boldsymbol{k}=\left(\mathbf{5 - 2 r _ { m }}\right) \boldsymbol{m}$ (Our Result)

Iterative phase: Assign smallest job of size $p$ to a machine $\boldsymbol{j}$ with load $\leq w_{j} \cdot\left(T+k-2\left(m-j^{\prime}\right) p\right)-p$, where $j^{\prime}=\max \left\{j,\left(r_{m}-1\right) m / r_{m}\right\}$

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

- Determine total buffer size $k$ : Apply the feasibility condition in the iterative phase
- At any time, there exists a machine $j$ with load $\leq \boldsymbol{w}_{j} \cdot\left(\boldsymbol{T}+\boldsymbol{k}-\mathbf{2}\left(\boldsymbol{m}-j^{\prime}\right) \boldsymbol{p}\right)-\boldsymbol{p}$, where $j^{\prime}=\max \left\{j,\left(r_{m}-1\right) m / r_{m}\right\}$

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

- Determine total buffer size $\boldsymbol{k}$ : Apply the feasibility condition in the iterative phase
- At any time, there exists a machine $j$ with load $\leq \boldsymbol{w}_{j} \cdot\left(\boldsymbol{T}+\boldsymbol{k}-\mathbf{2}\left(\boldsymbol{m}-j^{\prime}\right) \boldsymbol{p}\right)-\boldsymbol{p}$, where $j^{\prime}=\max \left\{j,\left(r_{m}-1\right) m / r_{m}\right\}$
- As shown previously, at least $\boldsymbol{m} \cdot \boldsymbol{p}$ space between the current load $\boldsymbol{T}$ and the designed profile will suffice

$$
\begin{array}{rlrl} 
& \sum w_{j} \cdot\left(T+k-2\left(m-j^{\prime}\right) p\right) \geq T+m \cdot p & \\

\leftarrow & T+k-2 m \cdot p+2\left(r_{m}-1\right) m \geq T+m \cdot p & & \left(\sum w_{j} \cdot j^{\prime} \geq\left(r_{m}-1\right) m\right) \\
\leftarrow & k \geq\left(5-2 r_{m}\right) m &
\end{array}
$$

## Buffer size $\boldsymbol{k}=\left(5-2 r_{m}\right) \boldsymbol{m}$ (Our Result)

- Determine total buffer size $k$ : Apply the feasibility condition in the iterative phase
- At any time, there exists a machine $j$ with load $\leq \boldsymbol{w}_{j} \cdot\left(\boldsymbol{T}+\boldsymbol{k}-\mathbf{2}\left(\boldsymbol{m}-j^{\prime}\right) \boldsymbol{p}\right)-\boldsymbol{p}$, where $j^{\prime}=\max \left\{j,\left(r_{m}-1\right) m / r_{m}\right\}$
- As shown previously, at least $\boldsymbol{m} \cdot \boldsymbol{p}$ space between the current load $\boldsymbol{T}$ and the designed profile will suffice

$$
\begin{array}{rlrl} 
& \sum w_{j} \cdot\left(T+k-2\left(m-j^{\prime}\right) p\right) \geq T+m \cdot p & \\
\leftarrow & T+k-2 m \cdot p+2 \sum w_{j} \cdot j^{\prime} \geq T+m \cdot p & & \left(\sum w_{j}=1\right) \\
\leftarrow & T+k-2 m \cdot p+2\left(r_{m}-1\right) m \geq T+m \cdot p & & \left(\sum w_{j} \cdot j^{\prime} \geq\left(r_{m}-1\right) m\right) \\
\leftarrow & k \geq\left(5-2 r_{m}\right) m &
\end{array}
$$

## Tradeoff: Comp. ratio vs Buffer size

Combining and extending our results with the ones from Englert et al. 2008

## Tradeoff: Comp. ratio vs Buffer size

Combining and extending our results with the ones from Englert et al. 2008

## Remarks

- Classical online makespan scheduling
- Comp. ratio for large $m$

| Upper Bound | - | 2 | (Graham 1966) |
| :---: | :---: | :---: | :---: |
|  |  | 1.986 | (Bartal et al. 1995) |
|  |  | 1.945 | (Karger et al. 1996) |
|  |  | 1.923 | (Albers 1999) |
|  | - | 1.9201 | (Fleischer et al. 2000) |
| Lower <br> Bound | - | .... |  |
|  | $\bigcirc$ | 1.88 | (Rudin III 2001) |
|  | - | 1.854 | (Gormley et al. 2000) |
|  |  | 1.852 | (Albers 1999) |
|  |  | 1.837 | (Bartal et al. 1994) |

- Semi-online scheduling with reordering buffer
- Buffer size needed to get opt. comp. ratio for large $m$
- $2.364 m$ (Englert et al. 2008)
- 2.068m (Our result)
$\qquad$

- $m$ ?
(Our work in progress)
- $0.5 m$ (Englert et al. 2008)

## Remarks

Semi-online scheduling with reordering buffer

- Buffer size needed to get opt. comp. ratio for large $m$
- $2.364 m$ (Englert et al. 2008)
- 2.068m (Our result)
- ....

- $m$ ?
- $0.5 m$
(Our work in progress)
(Englert et al. 2008)

## A similar problem

- Semi-online scheduling with job migrations
- Problem
- Online algorithm is allowed to perform a limited number (independent of input size) of job migrations
- Results (Albers and Hellwig 2012)
- For general $m$, optimal comp. ratio (lower bound) $=r_{m}$ (Identical to the case with reordering buffer)
- An algorithm that achieves $r_{m}$-comp. with $\left[\left(2-r_{m}\right) /\left(r_{m}-1\right)^{2}+4\right] m \approx 7 m$ migrations for large $m$
- Results with migration can be transformed into results with reordering buffer, but not vise versa

## A similar problem

- Semi-online scheduling with job migrations
- Problem
- Online algorithm is allowed to perform a limited number (independent of input size) of job migrations
- Results (Albers and Hellwig 2012)
- For general $m$, optimal comp. ratio (lower bound) $=r_{m}$ (Identical to the case with reordering buffer)
- An algorithm that achieves $r_{m}$-comp. with $\left[\left(2-r_{m}\right) /\left(r_{m}-1\right)^{2}+4\right] m \approx 7 m$ migrations for large $m$
- Results with migration can be transformed into results with reordering buffer, but not vise versa
$\square$ What is min. no. of migrations required? Can the existing result be improved to maintain the optimal comp. ratio?

## Thanks for your attention!
