<u>Chapter - 7 Power Dividers</u> <u>and Couplers</u>

One of the most fundamental problems in microwave engineering is how to efficiently divide signal power.

The simplest microwave problem would seemingly be to equally divide signal power in two:

However, building these devices is more difficult than you might think!

7.1 - Basic Properties of

Dividers and Couplers

Reading Assignment: pp. 308-315

First let's examine four-port networks called **directional couplers**, and explain some fundamental values that characterize them.

HO: THE DIRECTIONAL COUPLER

1/11

The Directional Coupler

A directional coupler is a 4-port network that is designed to divide and distribute power.

Although this would seem to be a particularly **mundane** and simple task, these devices are both very **important** in microwave systems, and very **difficult** to design and construct.

Two of the **reasons** for this difficulty are our desire for the device to be:

- 1. Matched
- **B**. Lossless

Thus, we require a **matched**, **lossless**, and (to make it simple) **reciprocal** 4-port device!

Recall that a matched, lossless, reciprocal, 4-port device was difficult to even **mathematically** determine, as the resulting scattering matrix must be (among other things) **unitary**.

However, we were able to determine two possible mathematical solutions, which we called the **symmetric** solution:

And the **asymmetric** solution:

$$\boldsymbol{\mathcal{S}} = \begin{bmatrix} 0 & \alpha & \beta & 0 \\ \alpha & 0 & 0 & -\beta \\ \beta & 0 & 0 & \alpha \\ 0 & -\beta & \alpha & 0 \end{bmatrix}$$

wherein for both cases, the relationship:

$$\alpha|^2 + |\beta|^2 = 1$$

must be true in order for the device to be **lossless** (i.e., for \mathcal{S} to be unitary).

For most couplers we will find that α and β can (at least ideally) be represented by a real value c, known as the **coupling coefficient**.

$$\beta = c$$
 $\alpha = \sqrt{1-c^2}$

The symmetric solution is thus described as:

Additionally, for a directional coupler, the coupling coefficient c will be less than $1/\sqrt{2}$ always. Therefore, we find that:

$$0 \leq c \leq rac{1}{\sqrt{2}}$$
 and $rac{1}{\sqrt{2}} \leq \sqrt{1-c^2} \leq 1$

Let's see what this means in terms of the **physical behavior** of a directional coupler. First, consider the case where some signal is incident on **port 1**, with power P_1^+ .

If all other ports are matched, we find that the power flowing out of **port 1** is:

$$P_1^- = |S_{11}|^2 P_1^+ = 0^2 P_1^+ = 0$$

while the power out of port 2 is:

$$P_2^- = |S_{21}|^2 P_1^+ = (1 - c^2) P_1^+$$

and the power out of **port 3** is:

$$P_{3}^{-} = |S_{31}|^2 P_{1}^{+} = c^2 P_{1}^{+}$$

Finally, we find there is no power flowing out of port 4:

$$P_4^- = |S_{41}|^2 P_1^+ = 0^2 P_1^+ = 0$$

In the terminology of the directional coupler, we say that port 1 is the **input** port, port 2 is the **through** port, port 3 is the **coupled** port, and port 4 is the **isolation** port.

Note however, that **any** of the coupler ports can be an input, with a different through, coupled and isolation port for each case.

For example, **if** a signal is incident on **port** 2, while all other ports are matched, we find that:

Thus, from the scattering matrix of a directional coupler, we can form the following table:

Input	Through	Coupled	Isolation
Port 1	Port 2	Port 3	Port 4
Port 2	Port 1	Port 4	Port 3
Port 3	Port 4	Port 1	Port 2
Port 4	Port 3	Port 2	Port 1

Typically, the coupling coefficients for a directional coupler are in the range of approximately:

$0.25 > c^2 > 0.0001$

As a result, we find that $\sqrt{1-c^2} \approx 1$. What this means is that the power out of the **through** port is just **slightly smaller** (typically) than the power incident on the input port.

Likewise, the power out of the **coupling** port is typically a **small fraction** of the power incident on the input port.

Q: *Pfft! Just a small fraction of the input power! What is the use in doing that??*

A: A directional coupler is often used for **sampling** a small portion of the signal power. For example, we might **measure** the output power of the **coupled** port (e.g., P_3^-) and then we can determine the amount of signal power flowing through the device (e.g., $P_1^+ = P_3^-/c^2$)

Unfortunately, the **ideal** directional coupler **cannot** be built! For example, the input match is never **perfect**, so that the diagonal elements of the scattering matrix, although **very small**, are not zero.

7/11

Likewise, the isolation port is never **perfectly** isolated, so that the values S_{41} , S_{32} , S_{23} and S_{14} are also non-zero—some **small** amount of power leaks out!

As a result, the through port will be slightly less than the value $\sqrt{1-c^2}$. The scattering matrix for a non-ideal coupler would therefore be:

$$\boldsymbol{\mathcal{S}} = \begin{vmatrix} S_{11} & S_{21} & jc & S_{41} \\ S_{21} & S_{11} & S_{41} & jc \\ jc & S_{41} & S_{11} & S_{21} \\ S_{41} & jc & S_{21} & S_{11} \end{vmatrix}$$

From this scattering matrix, we can extract some important parameters about directional couplers:

<u>Coupling</u> C

The **coupling** value is the ratio of the coupled output power (P_3^-) to the input power (P_1^+) , expressed in decibels:

$$\mathcal{C}(dB) = 10\log_{10}\left|\frac{P_{1}^{+}}{B^{-}}\right| = -10\log_{10}\left|jc\right|^{2}$$

This is the **primary** specification of a directional coupler!

Note the **larger** the coupling value, the **smaller** the coupled power! For example:

A 6 dB coupler couples out 25% of the input power.

A 10 dB coupler couples out 10% of the input power.

A 20 dB coupler couples out 1.0% of the input power.

A 30 dB coupler couples out 0.1% of the input power.

Directivity D

The **directivity** is the ratio of the power **out** of the coupling port (P_3^-) to the power **out** of the isolation port (P_4^-), expressed in decibels.

$$\mathcal{D}(dB) = 10\log_{10}\left[\frac{P_{3}^{-}}{P_{4}^{-}}\right] = 10\log_{10}\left[\frac{|jc|^{2}}{|S_{41}|^{2}}\right]$$

This value indicates how effective the device is in "**directing**" the coupled energy into the correct port (i.e., into the coupled port, **not** the isolation port).

Ideally this is infinite (i.e., $P_4^- = 0$), so the higher the directivity, the better.

Isolation I

Isolation is the ratio of the **input power** (P_1^+) to the power out of the **isolation** port (P_4^-) , expressed in decibels.

$$I(dB) = 10\log_{10}\left|\frac{P_{1}^{+}}{P_{4}^{-}}\right| = -10\log_{10}\left[|S_{41}|^{2}\right]$$

This value indicates how "isolated" the isolation port actually is. **Ideally** this is infinite (i.e., $P_4^- = 0$), so the **higher** the isolation, the better.

Note that isolation, directivity, and coupling are **not** independent values! **You** should be able to quickly show that:

$$I(dB) = C(dB) + D(dB)$$

Mainline Loss ML

The mainline loss is the ratio of the input power (P_1^+) to the power out of the through port (P_2^-) , expressed in decibels.

$$ML(dB) = 10\log_{10}\left[\frac{P_1^+}{P_2^-}\right] = -10\log_{10}\left[|S_{21}|^2\right]$$

It indicates how much power the signal **loses** as it travels from the input to the through port.

Coupling Loss ML

The **coupling loss** indicates the **portion** of the mainline loss that is due to coupling some of the input power into the coupling port.

$$CL(dB) = 10\log_{10}\left|\frac{P_1^+}{P_1^+ - P_3^-}\right| = -10\log_{10}\left[1 - |jc|^2\right]$$

Conservation of energy makes this loss is **unavoidable**. Note this value can be **very small**, for example:

The coupling loss of a 10dB coupler is 0.44 dB

The coupling loss of a 20dB coupler is 0.044 dB

The coupling loss of a 30dB coupler is 0.0044 dB

Insertion Loss IL

Q: But wait, shouldn't $P_1^+ - P_3^- = P_2^-$, meaning the coupling loss and the mainline loss will be the same exact value?

A: Ideally this would be true.

But, the reality is that couplers are **not perfectly lossless**, so there will additionally be loss due to **absorbed** energy (i.e., heat). This loss is called **insertion loss** and is simply the **difference** between the mainline loss and coupling loss:

IL(dB) = ML(dB) - CL(dB)

The insertion loss thus indicates the portion of the mainline loss that is **not** due to coupling some input power to the coupling port. This insertion loss **is** avoidable, and thus the **smaller** the insertion loss, the better.

For couplers with very small coupling coefficients (e.g., C(dB) > 20) the coupling loss is so small that the mainline loss

is almost entirely due to insertion loss (i.e., ML = IL)—often then, the two terms are used interchangeably.
